1 Gene network

- Each node corresponds to a gene
- Each edge corresponds to a pair of genes which are ‘co-expressed’

‘co-expressed’ meaning that their expression levels are highly correlated. The weights represent the strength of the connection between two genes.

True correlation between gene m, n ρ_{mn} and correlation by observed data is $r_{mn} = \text{corr}(x_m, x_n)$ by Fisher’s z-transformation $w_{mn} = \text{arctanh}(r_{mn})$ approximately normal distribution .

$$w_{mn} \sim N(\text{arctanh}(\rho_{mn}), \frac{1}{N-3}) \quad (1)$$

Let $E = \{e_{mn}\}$ be a set of true edges in the network.

The number of Gene G is larger and that most pairs are not co-expressed, and the number of possible edge $K = G(G-1)/2$ is very larger than the number of true edges in the network $|E|$

So in this gene network model we have some assumption

- This graphical model is undirected model because each node means correlation
- The network can be cycle??
- The network is sparse ($|E| \ll K$)

- The weight w_{mn} follows L_2N model

L_2N model is a three component mixture model. First the 'null' component follow normal distribution with mean 0, which means majority of correlation between genes are 0. And the 'not null' components which mean strong positive/negative correlation follow log-normal distribution each.

Figure 1: L_2N model

$$w_{mn}|e_{mn} \notin E \sim N(0, \sigma^2) \quad (2)$$

$$w_{mn}|[w_{mn} > 0, e_{mn} \in E] \sim \text{LogNormal}(\theta_1, \kappa_1^2) \quad (3)$$

$$-w_{mn}|[w_{mn} < 0, e_{mn} \in E] \sim \text{LogNormal}(\theta_2, \kappa_2^2) \quad (4)$$

$\sigma^2 = 1/(N - 3) + \sigma_0^2$, where $1/(N - 3)$ from Fisher's z-transformation and σ_0^2 from random effect model. Let C_0, C_1, C_2 means the distribution in the mixture model C_0 the null component, C_1, C_2 the 2 not null components.

$$Pr(e_{mn} \in C_j | w_{mn}) = \frac{P_j f_j(w_{mn})}{P_0 f_0(w_{mn}) + P_1 f_1(w_{mn}) + P_2 f_2(w_{mn})} \quad (5)$$

$\mathbf{b}_{mn} = (b_{mn0}, b_{mn1}, b_{mn2})$ means the indicator vector $b_{mnj} = 1$ when the $Pr(e_{mn} \in C_j | w_{mn})$ has the highest probability and 0 for the other two. Make adjacency $G \times G$ matrix \mathbf{A} , where $\mathbf{A}_{mn} = 1 - b_{mn0}$
